Short Report:

Perceived discrimination in minority and matched non-minority adolescents in Ireland

András Költő, Aoife Gavin, Colette Kelly, Michal Molcho and Saoirse Nic Gabhainn

<https://doi.org/10.13025/YDPB-CQ72>

Introduction

Young people belonging to some population sub-groups are more likely to face discrimination than their peers who are not (Grollman, 2012). Children and adolescents are more vulnerable to the negative consequences of discrimination than adults (Schmitt, Branscombe, Postmes, & Garcia, 2014). Experiences of discrimination in adolescence are associated with poor psycho-social adjustment, school adjustment and academic performance (Hood, Bradley, & Ferguson, 2017). The grounds of discrimination include, among others, sexual orientation (Almeida, Johnson, Corliss, Molnar, & Azrael, 2009), disability or chronic conditions (Heary, Hennessy, & Swords, 2014), immigrant status or belonging to a racial minority (Mesch, Turjeman, & Fishman, 2008), and belonging to ethnic or cultural minority groups such as Roma (Kolarcik, Geckova, Reijneveld, & Van Dijk, 2015). Young people from certain population sub-groups, or minorities, are not only more likely to be discriminated on the basis of being in that group, but also experience discrimination on other grounds. For instance, sexual minority children in Ireland were significantly more likely than their non-minority peers to report discrimination not only because of their sexual orientation but also because of their place of birth, gender, age, disability status, race, or religion (Költő et al., 2021). However, to our knowledge there have been no comprehensive studies that documented perceived discrimination among adolescents in Ireland. In this short report, we present the rates of perceived discrimination on various grounds in adolescents aged 12-17, participating in the 2018 data collection round of the nationally representative Health Behaviour in School-aged Children (HBSC) study.

The HBSC is a cross-national research study conducted in collaboration with the World Health Organisation (WHO) Regional Office for Europe and runs on a four-year cycle. In 2018, Ireland participated for the sixth time in the HBSC study (www.nuigalway.ie/hbsc). The overall aims of the

HBSC study are to gain new insight into, and increase our understanding of young people's health and well-being, health behaviours and their social context. HBSC collects data on key indicators of health, health attitudes, and health behaviours, as well as the context of health for young people. The study is a school-based survey with information collected from students through self-completion questionnaires in classrooms. HBSC Ireland 2018 was funded by the Department of Health. Further information on the HBSC Ireland can be found at www.nuigalway.ie/hbsc or at www.hbsc.org, the International HBSC website.

The most recent HBSC Ireland study was conducted in 2018. The methods employed comply with the International HBSC protocol and are detailed in the national report from the 2018 survey (Költő et al., 2020). This report presents the frequency of perceived discrimination on the basis of (1) where they, their parents or grandparents were born, (2) they are a boy or a girl, (3) their age, (4) their disability, (5) their race, (6) their sexual orientation, (7) their religion, and (8) being member of the Traveller community, by age group, gender, and social class. Frequency of perceived discrimination among minority groups and their non-minority peers are also compared. Minority and non-minority youth were matched by age, gender and social class, to ensure differences in these socio-demographic characteristics do not confound the comparisons.

Method

This short report presents findings from adolescents aged 12-17 years who answered the items on perceived discrimination ($5995 \leq n \leq 6034$). Frequency of perceived discrimination based on the eight different grounds was assessed with individual Likert-type questions. Children were asked how often they were treated unfairly or negatively because of their place of birth or that of their parents or grandparents, their age, gender, age, disability, race, sexual orientation, religion and membership of the Traveller community¹. The response options ranged from 'Never' =1 to 'Very often' = 5.

The associations between frequency of perceived discrimination and age group, gender and social class were investigated in the full sample, and are presented below.

To compare the rates of perceived discrimination in minority and non-minority children, an iterative case-control matching technique was applied. In order to eliminate the potential confounding effect

¹ Children were also asked whether they have ever been discriminated based on any other grounds, and they were provided with a text box to give the reason(s). This basis of discrimination is not included here.

of sociodemographic differences, adolescents who had reported being a member of a minority group ('cases') were matched with a non-minority peer of the same age group, gender and social class ('controls'). First, we tried to identify the non-minority matched peer within the same school class. If there was no suitable match, we searched for a matched control in the same school. If no match was identified within the school, we extended the search to the same county. If no match was found within the county, we continued the search within the respective geographical region. If no match was found within the same region, the case was deemed unmatched.

Four matched datasets were created for adolescents who reported (a) belonging to sexual minority, (b) living with a disability or chronic condition, labelled as 'disability' below (c) first generation immigrant status, labelled 'immigrant' below, and (d) membership of the Traveller community, labelled 'Traveller' below.

The associations between frequency of perceived discrimination and membership of the four minority groups were investigated and are presented below. The associations were tested using Chi-square tests. The threshold of statistical significance was set at $p < .05$. To demonstrate the magnitude of the effects, we calculated Cramér's V effect sizes. Following Cohen's (1988) guidelines, effects $V \leq .10$ interpreted as negligible, V between .10 and .29 as small, V between .30 and .49 as medium and $V \geq .50$ as large.

Findings

Perceived discrimination based on place of birth of the respondent, their parents or grandparents

Table 1 presents the associations between frequency of perceived discrimination on the basis of birthplace of the participant, parents or grandparents and sociodemographic factors in the overall sample. In sum, 25.9% of the children reported ever being discriminated against on the basis of their, their parents' or grandparents' place of birth. Age group was not significantly associated with perceived discrimination. A significant association was found with gender: slightly more boys than girls reported ever being discriminated on this basis, but the effect size was negligible. Similarly, children from lower social class groups were more likely to report discrimination than their peers from higher social classes, but the effect size was negligible.

Table 2 presents associations between perceived discrimination on the basis of birthplace of the participant, their parents or grandparents and belonging to different minorities. Sexual minority children were significantly more likely to report discrimination on the basis of birthplace than their non-minority peers, but the effect size was small. Discrimination was not significantly associated

with living with a disability or chronic condition, or being a member of the Traveller community. Immigrant children were more likely than their non-immigrant peers to report ever being discriminated on the basis of their birthplace or that of their parents or grandparents and the effect size was medium.

Perceived discrimination on the basis of place of birth of the respondent, their parents or grandparents

Note. Sample sizes across matched groups differ due to the different size of minority groups. Significant associations ($p < .05$) are highlighted in bold.

Perceived discrimination based on gender

Table 3 presents the associations between frequency of perceived discrimination on the basis of the respondent's gender in the overall sample. In sum, 38.9% of the children reported ever being discriminated against on the basis of their gender. Age group was significantly associated with perceived discrimination, with older children more likely to report discrimination, but the effect was negligible. A significant association was found with gender: more girls than boys reported ever being discriminated on this basis, with a medium effect size. Discrimination on the basis of gender was not significantly associated with social class.

Table 4 presents associations between perceived discrimination on the basis of gender and belonging to different minorities. Sexual minority children were significantly more likely to report discrimination on the basis of gender, but the effect size was small. Children with disabilities and chronic conditions and immigrant children were also significantly more likely to report discrimination on the basis of their gender than their non-minority counterparts, but the effect sizes were negligible. Discrimination on the basis of gender was not significantly associated with Traveller status.

Perceived discrimination on the basis on the respondent's gender

Traveller	57.3% (67)	19.7% (23)	14.5% (17)	3.4% (4)	5.1% (6)	117		
Non-Traveller	65.8% (77)	19.7% (23)	10.3% (12)	2.6% (3)	1.7% (2)	117		

Note. Sample sizes across matched groups differ due to the different size of minority groups. Significant associations ($p < .05$) are highlighted in bold.

Perceived discrimination based on age

Table 5 presents the associations between frequency of perceived discrimination on the basis of the respondent's age in the overall sample. In sum, 47.3% of the children reported ever being discriminated against on the basis of their age. Age group was significantly associated with perceived discrimination, with older children more likely to report discrimination, but the effect was negligible. A significant association was found with gender: more girls than boys reported ever being discriminated on this basis, with a medium effect size. Discrimination on the basis of age was not significantly associated with social class.

Table 6 presents associations between perceived discrimination on the basis of age and belonging to different minorities. Sexual minority children were significantly more likely to report discrimination on the basis of age, but the effect size was small. Children living with disabilities or chronic conditions were also significantly more likely to report discrimination on the basis of their age than their non-minority counterparts, but the effect size was negligible. Discrimination on the basis of age was not significantly associated with immigrant or Traveller status.

Perceived discrimination on the basis on the respondent's age

Sexual minority							<.000	.161
Sexual minority	37.3% (194)	22.3% (116)	22.9% (119)	11.5% (60)	6.0% (31)	520		
Non-minority	51.5% (268)	20.0% (104)	15.0% (78)	10.6% (55)	2.9% (15)	520		
Disability							.032	.063
Disability	50.1% (656)	17.9% (234)	19.6% (256)	8.6% (113)	3.8% (50)	1309		
No disability	54.4% (712)	18.8% (246)	17.4% (228)	7.0% (91)	2.4% (32)	1309		
Immigrant							.862	.028
Immigrant	54.5% (454)	19.6% (163)	16.4% (137)	6.6% (55)	2.9% (24)	833		
Non-immigrant	54.0% (450)	20.0% (167)	17.5% (146)	6.2% (52)	2.2% (18)	833		
Traveller							.446	.127
Traveller	51.3% (59)	20.9% (24)	15.7% (18)	6.1% (7)	6.1% (7)	115		
Non-Traveller	61.7% (71)	18.3% (21)	11.3% (13)	6.1% (7)	2.6% (3)	115		

Note. Sample sizes across matched groups differ due to the different size of minority groups. Significant associations ($p < .05$) are highlighted in bold.

Perceived discrimination based on disability

Table 7 presents the associations between frequency of perceived discrimination on the basis of the respondent's disability in the overall sample. In sum, 9.7% of the children reported ever being discriminated against on the basis of their disability. Age group was not significantly associated with perceived discrimination. A significant association was found with gender: more boys than girls reported ever being discriminated on this basis, but the effect size was negligible. Discrimination on the basis of disability was not significantly associated with social class.

Table 8 presents associations between perceived discrimination on the basis of disability and belonging to different minorities. Sexual minority was not significantly associated with discrimination on the basis of disability. Children with disabilities or chronic conditions were significantly more likely to report discrimination on the basis of their disability than their non-minority counterparts, but the effect size was small. Discrimination on the basis of disability was not significantly associated with immigrant status. Children belonging to the Traveller community were significantly more likely than their non-Traveller counterparts to be discriminated based on disability, with a small effect size.

Traveller							.004	.263
Traveller	77.0% (87)	9.7% (11)	4.4% (5)	1.8% (2)	7.1% (8)	113		
Non-Traveller	93.8% (106)	1.8% (2)	3.5% (4)	0.0% (0)	0.9% (1)	113		

Note. Sample sizes across matched groups differ due to the different size of minority groups. Significant associations ($p < .05$) are highlighted in bold.

Perceived discrimination based on race

Table 9 presents the associations between frequency of perceived discrimination on the basis of the respondent's race in the overall sample. In sum, 14.2% of the children reported ever being discriminated against on the basis of their race. Age group, gender and social class were not significantly associated with perceived discrimination on the basis of the respondent's race.

Table 10 presents associations between perceived discrimination on the basis of race and belonging to different minorities. Children identifying as sexual minority, and those living with disability or chronic condition did not report significantly different rates discrimination on the basis of race than their matched non-minority peers. Discrimination on the basis of race was significantly associated with immigrant status: immigrant children were more likely to report discrimination on this basis than their matched counterparts, with a medium effect size. Discrimination on the basis of race was significantly associated with being a member of the Traveller community: Traveller children were more likely to report discrimination on this basis than non-Traveller children, with a small effect size.

Perceived discrimination on the basis on the respondent's race

Table 9. Rates of perceived discrimination on the basis of race in the overall sample

Non-Traveller	85.8% (97)	5.3% (6)	5.3% (6)	2.7% (3)	0.9% (1)	113		

Note. Sample sizes across matched groups differ due to the different size of minority groups. Significant associations ($p < .05$) are highlighted in bold.

Perceived discrimination based on sexual orientation

Table 11 presents the associations between frequency of perceived discrimination on the basis of the respondent's sexual orientation in the overall sample. In sum, 11% of the children reported ever being discriminated against on the basis of their sexual orientation. Age group was not significantly associated with perceived discrimination on this basis. There was a significant association with gender: girls were more likely than boys to report being discriminated against on the basis of their sexual orientation, but the effect size was negligible. No significant association was found between discrimination on this basis and social class.

Table 12 presents associations between perceived discrimination on the basis of sexual orientation and belonging to different minorities. Sexual minority status was significantly associated with discrimination on the basis of sexual orientation: minority children were more likely to report being discriminated against, with a large effect size. Discrimination on the basis of sexual orientation was not significantly associated with having a disability or chronic condition. A significant association was found with immigrant status: immigrant children were more likely to be discriminated against on the basis of their sexual orientation, but the effect was negligible. Traveller children were also more likely to report discrimination on this basis than non-Traveller children, with a small effect size.

Note. Sample sizes across matched groups differ due to the different size of minority groups. Significant associations ($p < .05$) are highlighted in bold.

Perceived discrimination based on religion

Table 13 presents the associations between frequency of perceived discrimination on the basis of the respondent's religion in the overall sample. In sum, 12.3% of the children reported ever being discriminated against on the basis of their religion. Age group, gender and social class were not significantly associated with perceived discrimination on the basis of the respondent's race.

Table 14 presents associations between perceived discrimination on the basis of religion and belonging to different minorities. Sexual minority status was significantly associated with discrimination on the basis of religion: minority children were more likely to report being discriminated against on this basis, with a small effect size. Discrimination on the basis of religion was not significantly associated with having a disability or chronic condition. A significant association was found with immigrant status: immigrant children were more likely to be discriminated against on the basis of their religion, with a small effect size. No significant association was detected between Traveller status and discrimination on the basis of religion.

Note. Sample sizes across matched groups differ due to the different size of minority groups. Significant associations ($p < .05$) are highlighted in bold.

Perceived discrimination based on membership of the Traveller community

Table 15 presents the associations between frequency of perceived discrimination on the basis of the respondent's membership of the Traveller community. In sum, 3.2% of the children reported ever being discriminated against on the basis of membership of the Traveller community. Age group was not significantly associated with perceived discrimination on the basis of the respondent's membership of the Traveller community. Boys were more likely to be discriminated on this basis than girls, but the effect size was negligible. No significant association was found between discrimination based on this basis and social class.

Table 16 presents associations between perceived discrimination on the basis of membership of the Traveller community and belonging to different minorities. Children identifying as sexual minority, immigrant children and those living with disability or chronic condition did not report significantly different rates discrimination on the basis of membership of the Traveller community than their matched peers. Membership of the Traveller community was significantly associated with discrimination: children belonging to the Traveller community were more likely to report discrimination due to their Traveller community membership than their non-Traveller counterparts, with a large effect size.

Perceived discrimination on the basis on the respondent's membership of the Traveller community

Discussion

To our knowledge, this is the first comprehensive report of perceived discrimination among Irish schoolchildren, in a nationally representative sample of children aged 12-17 as well as in four minority groups: sexual minority children, children with a disability or chronic condition, first-generation immigrant children, and children belonging to the Traveller community. Children belonging to the four minority groups were compared to a non-minority sample matched for age, gender, social class and location.

The general pattern of the results show that perceived discrimination was associated with socio-demographic characteristics, especially gender, although many of these effects had negligible or low effect sizes. Girls were more likely than boys to report being discriminated against based on six of the eight grounds, with gender and age being particularly salient basis for discrimination against them. This pattern highlights the power imbalance and the gender injustice that pervades Irish society (Mooney Cotter, 2016).

In minority children, we also observed multiple discrimination, not only based on the grounds on their own minority (e.g. Travellers being discriminated on the basis of membership of the Traveller community) but on several other grounds. Sexual minority children were more likely than their peers to report discrimination based on not only their sexual orientation, but also on the basis of place of birth, gender, age and religion. In addition to being discriminated against due to disability, children with a disability or chronic condition were more likely than their matched peers to report discrimination based on gender and age. First generation immigrant children, in addition to being discriminated due to their (or their ascendants') place of birth, were also more likely than non-immigrant children to report discrimination based on their gender, race, sexual orientation and religion. Traveller children, on the top of being discriminated against based on their Traveller status, were also more likely than non-travellers to report discrimination based on their disability and race. This phenomenon reflects a 'negative halo effect', meaning that one characteristic seen as negative or undesirable sheds a negative light on the whole person (Költő et al., 2021). The results presented here mark the vulnerability of girls and minority children to being discriminated against.

We believe that the study is strengthened by the nationally representative sample and the established HBSC methodology, which has guided the HBSC Ireland Team's work since 1997 (Gavin, Költő, Kelly, Molcho, & Nic Gabhainn, 2021). A limitation to the study, however, is that the matched non-minority groups are not cleaned for other minorities (i.e. a non-immigrant child selected as a control for a matched immigrant child could be sexual minority or have a disability or chronic

condition). Such data cleaning would probably would have resulted in even lower subsample sizes, and less stable analysis outcomes.

Acknowledgement

HBSC Ireland 2018 was funded by the Department of Health. This short report was requested by James Shaw (Department of Children, Equality, Disability, Inclusion and Youth) and was completed in November 2021. We would like to acknowledge the children and parents who consented and participated, the management authorities, principals and teachers who helped us to collect the data, the staff at the Health Promotion Research Centre, National University of Ireland Galway, the HBSC Ireland Advisory Board and the International coordinator of HBSC, Dr Jo Inchley of the University of Glasgow, Scotland. Further information on HBSC Ireland, and access to all study outputs, is available at www.nuigalway.ie/hbsc.
